## Description

### Erythropoietin Production Potentiator

#### Technical Field

The present invention relates to an erythropoietin production potentiator, and more particularly to a preventive or therapeutic agent for pathological conditions caused by reduced production of erythropoietin, such as anemia.

#### Background Art

Erythropoietin (EPO) is a glycoprotein hormone, which participates in maturation and differentiation of an erythroid progenitor cell to a matured red blood cell. EPO is a 165-amino-acid polypeptide, which is found in nature in the form of a monomer [Lin, F-K. et al., Proc. Natl. Acad. Sci. USA 82:7580-7584 (1985)].

Human erythropoietin plays a key role in proliferation and differentiation of red blood cells. Therefore, the hormone is useful for treatment of blood diseases primarily involving reduced production of red blood cells. Clinically, EPO is used in treatment of anemia associated with chronic renal failure (CRF), autologous blood storage, or anemia of prematurity (Eschbach JW, Egrie JC, Downing MR, et al., NEJM, 316:73-78 (1987); Eschbach JW, Abdulhadi MH, Browne JK et al., Ann. Intern. Med., 111:992 (1989); Egrie JC, Eschbach JW, McGuire T, Adamson JW, Kidney Intl., 33:262 (1988); and Lim VS, Degowin RL, Zavala D, et al., Ann. Intern. Med., 110:108-114 (1989)). EPO is also used in treatment of patients suffering AIDS or patients having cancer and receiving chemotherapy (Danna RP, Rudnick SA, Abels RI, Garnick MB, Erythropoietin in Clinical Applications - An International Perspective, New York: Marcel Dekker; 1990, pp. 301-324). EPO has been found to be effective in treatment of chronic anemia.

Some protein used for therapy such as EPO has a short plasma half-life and is susceptible to degradation in the presence of protease [Spivak JL and Hogans BB, Blood, 73:90 (1989); McMahon FG et al., Blood, 76:1718 (1990)]; i.e., EPO exhibits poor bioavailability. Accordingly, in a protein therapy employing EPO, intravenous injection must be performed frequently in order to maintain the effective therapeutic

blood level of the protein in circulation. Subcutaneous injection may be an alternative administration route. However, when administered subcutaneously, the agent is absorbed slowly from the administration site. Thus, plasma level of the protein is significantly low as compared with the case of intravenous administration, although effect of sustained release may be appreciable. Therefore, in order to obtain a therapeutic effect of similar level, subcutaneous injection must be performed frequently as in the case of intravenous administration.

Accordingly, demand exists for a method for potentiating erythropoietin production through administration of a compound other than erythropoietin, which exhibits poor bioavailability.

The present invention further provides use of the cyclic amino compound of formula (1), a salt thereof or solvates thereof for the preparation of a preventive or therapeutic agent for diseases caused by the lowering of an erythropoietin production.

#### Referential Example 226

Synthesis of

4-[N-[3-(3,4,5-trimethoxyphenyl)benzyl]-N-[4-(methylsulfonyl)phenyl]amino]piperidine:

4-[N-[3-(3,4,5-Trimethoxyphenyl)benzyl]-N-[4-(methylthio)phenyl]amino]-piperidine hydrochloride (52mg, prepared in Referential Example 145) was dissolved in dichloromethane (1mL) and 3-chloroperbenzoic acid (69mg) was added to the resulting solution at 0°C. After the mixture was allowed to cool to room temperature and stirred for 3 hours, a saturated sodium hydrogen carbonate solution was added thereto. After separating an organic layer, an aqueous layer was further extracted with chloroform. Combined organic layers were washed with saturated brine, dried over anhydrous sodium sulfate, and concentrated under reduced pressure. The resulting pale yellow oil was used in the next step without purification.

##### A. Materials and methods

Hep3B cells producing EPO under hypoxic condition were used. The cells were inoculated onto a 100 mm petri dish by  $1.5 - 3.0 \times 10^6$ . As a culture medium, 10 ml of Dulbecco's Modified Eagles' Medium (DMEM)/10 % Fetal Calf Serum (FCS) was used. The next day, the culture medium was exchanged, and compound of Preparation Example 13 (final concentration: 100 nM) was added, then cells were cultured under 1 % O<sub>2</sub> at 37 °C for 24 hrs. Groups were prepared in which IL-1β (final concentration: 15 U/ml) or TNF-α (final concentration: 220 U/ml), of which EPO production suppressing action is known (Faquin WC, Schneider TJ, Goldgerg MA, Blood, 79(8):1987-94(1992)), were used solely or in combination with compound of Preparation Example 13 (final concentration: 100 nM). As a control, a group that does not contain any agents was prepared. The amount of EPO in the supernatant obtained after the culture was measured by ELISA (each group; n = 3). The enhancer site and promoter site (144 bp) of a human EPO gene were linked to luciferase reporter vector, which was used for measuring the EPO promoter activity. The EPO promoter activity was evaluated as follows.

$1 \times 10^6$  Hep3B cells were inoculated on 30 mm petri dish (4 mL:DMEM/10 % FCS), and a reporter gene (2 μg) as well as β-galactosidase gene (1 μg) as an internal standard were transfected into the cells by the lipofectin method. The next day, the culture medium was exchanged and the groups, whose group-composition was similar to the above (control group (containing no agents), IL-1β group (final concentration: 15

U/ml), TNF- $\alpha$  (final concentration: 220 U/ml), compound of Preparation Example 13 (final concentration: 100 nM), or a combination of compound of Preparation Example 13 and IL-1 $\beta$  or TNF- $\alpha$ ) were cultured under 1 % O<sub>2</sub> or 21 % O<sub>2</sub> (as a control) at 37 °C for 24 hrs (for each group; n=4). The extract of the cells after cultured were prepared, then luciferase activity and  $\beta$  galactosidase activity were measured. The EPO promoter activity was expressed by the formula:

$$\text{HI (Hypoxic Induction)} = \frac{1 \% \text{ O}_2 \text{ luciferase}/\beta \text{ galactosidase}}{21 \% \text{ O}_2 \text{ luciferase}/\beta \text{ galactosidase}}$$

The data obtained were analyzed and evaluated by Student's t-test.

## B. Results

Fig. 1 shows the effect of addition of agents on the amount of the EPO protein produced by Hep3B cells under hypoxia (1 % O<sub>2</sub>). While the amount of the produced EPO protein of control was 424.3 $\pm$ 43.0 mU/mg protein, that of the group containing compound of Preparation Example 13 (final concentration: 100 nM) was increased to 829.8 $\pm$ 119.0 mU/mg protein, which is twice as much as the control. When IL-1 $\beta$  (15 U/ml) or TNF- $\alpha$  (220 U/ml) was added, the produced amount of EPO protein were reduced to 233.3 $\pm$ 19.4 mU/mg protein, 180.8 $\pm$ 24.6 mU/mg protein, respectively. But addition of compound of Preparation Example 13 (final concentration: 100 nM) in combination made it rescued to 395.0  $\pm$  72.6 mU/mg protein and 284.8  $\pm$  24.2 mU/mg protein, respectively.

Fig. 2 shows human EPO promoter activity. While the HI of the control was 33.7  $\pm$  4.8 fold, it was significantly increased to 46.1  $\pm$  5.9 fold by the addition of 100 nM of the Preparation Example 13 compound to the control. Although the addition of IL-1 $\beta$  (15 U/ml) or TNF- $\alpha$  (220 U/ml) suppressed the HI to 19.9  $\pm$  6.5, 20.7  $\pm$  4.1 fold, respectively, the simultaneous use of the Preparation Example 13 compound (100 nM) changes it to 45.5  $\pm$  7.1 fold, 49.5  $\pm$  5.4 fold, respectively, meaning that the addition produces not only release of the suppress, but also a significant increase thereof.

These results reveal that the Preparation Example 13 compound can increase EPO production from Hep3B cells under hypoxic condition, and that this increase is caused through transcription process of the gene.

## Test example 2

### A. Materials and methods

Hep3B cells were inoculated by  $1 \times 10^6$  on each of 6 cm dishes, and then cultured for 24 hrs. As a culture medium, 3 mL of DMEM/10 % FCS was used. The culture medium was exchanged and the compounds of each of Preparation Examples 13, 23, 29, 36, and 114 were added such that the content thereof was 100 nM final concentration, and they were transferred into the atmosphere of 1 % oxygen at 37 °C for further 24 hrs culture thereof. The supernatant of the culture was recovered, and the amount of EPO was measured by ELISA kit (product of Roche Diagnostics) (two cases in each group). Further, cell extract was prepared and protein amount was determined, and corrected it as production amount per protein amount. As a control, groups not containing the compounds are prepared.

### B. Results

Table 1 shows the effect of the compounds on the amount of the EPO produced in the Hep3B cell culture medium under 1 % oxygen. The addition of each compound (100 nM) gave 1.3-2.3 fold production of EPO compared to the control.

## Test example 3 (*in vivo* mice anemia model)

### A. Materials and methods

ICR mice (available from CLEA Japan Inc.) were made to be anemia by taking blood samples by 0.3 mL at a time from the orbital vein of the mouse by use of a heparin-coated microcapillary by 4 times in every 12 hours from 2 days before administering the agents. Further,  $1.67 \times 10^4$  unit/day of mouse IL-1 $\beta$  (Roche Diagnostics) or  $3.33 \times 10^5$  unit/day of mouse TNF- $\alpha$  (Roche Diagnostics) was injected intraperitoneally on day 0-3 (the first day of administration of agents was defined as day 0) to induce a suppressed condition of EPO production. To these mice, Preparation Example 13 compound dissolved in 50 % polyethylene glycol solution was administered orally by 1 or 3 mg/kg/day on day 0-5. As a control, 50 % polyethylene

glycol solution was administered (each group; n=7-15). On day 3 and 6, 0.3 mL of blood was collected, and hematocrit (Ht) value, hemoglobin (Hb) concentration (Celltac  $\alpha$ : NIHON KOHDEN), EPO amount (ELISA kit: Roche Diagnostics) were measured. Also, the blood was stained by methylene-blue, and smears were prepared to calculate Reticulocytes value.

## B. Results

Fig. 3 shows the effect of the compounds on Ht value of anemia model mice. In the Figure, a column indicates [average value + standard deviation]. While Ht of control group on day 3 was  $42.2 \pm 3.6 \%$ , it was significantly reduced, by IL-1 $\beta$  administration or TNF- $\alpha$  administration, to  $36.0 \pm 3.0 \%$ ,  $38.3 \pm 2.5 \%$ , respectively. In contrast thereto, the oral administration of Preparation Example 13 compound by 1 or 3 mg/kg/day improved to  $37.5 \pm 2.5 \%$ ,  $37.5 \pm 3.1 \%$  (IL-1 $\beta$ ) and  $38.8 \pm 2.0 \%$ ,  $40.0 \pm 2.7 \%$  (TNF- $\alpha$ ), respectively. Similarly on day 6, while Ht value of the control group was  $46.4 \pm 2.9 \%$ , the administration of IL-1 $\beta$  or TNF- $\alpha$  provided significant reduction of  $40.9 \pm 1.5 \%$ ,  $41.6 \pm 1.8 \%$ , respectively. In contrast, the oral administration of Preparation Example 13 compound by 1 or 3 mg/kg/day improved to of  $42.6 \pm 2.5 \%$ ,  $43.3 \pm 2.8 \%$  (IL-1 $\beta$ ), respectively, and  $43.3 \pm 2.5 \%$ ,  $43.2 \pm 2.2 \%$  (TNF- $\alpha$ ), respectively. In particular, it is observed that in the IL-1 $\beta$  administration group, the Ht value by the administration of Preparation Example 13 compound was significantly improved both in 1 and in 3 mg/kg/day.

While Hb of control group on day 3 was  $13.8 \pm 0.6$  g/dL, it was significantly reduced, by IL-1 $\beta$  administration or TNF- $\alpha$  administration, to  $12.3 \pm 0.8$  g/dL,  $12.6 \pm 0.7$  g/dL, respectively. In contrast thereto, the oral administration of Preparation Example 13 compound by 1 or 3 mg/kg/day improved to  $12.7 \pm 0.7$  g/dL,  $12.6 \pm 1.0$  g/dL (IL-1 $\beta$ ), and  $12.8 \pm 0.6$  g/dL,  $13.1 \pm 0.8$  g/dL (TNF- $\alpha$ ), respectively. Similarly, on day 6, while Hb of control group was  $14.8 \pm 0.8$  g/dL, it was significantly reduced, by IL-1 $\beta$  administration or TNF- $\alpha$  administration, to  $13.5 \pm 0.5$  g/dL,  $13.1 \pm 0.5$  g/dL, respectively. In contrast thereto, the oral administration of Preparation Example 13 compound by 1 or 3 mg/kg/day significantly improved to  $14.1 \pm 1.1$  g/dL,  $14.0 \pm 0.9$  g/dL (IL-1 $\beta$ ), and  $14.0 \pm 0.6$  g/dL,  $13.8 \pm 0.5$  g/dL (TNF- $\alpha$ ), respectively.

Fig. 5 shows the number of reticulocytes. In this figure, the value of the column indicates [average value + standard deviation]. While the reticulocyte value of control group on day 3 was  $32.1 \pm 4.4 \%$ , the administration of IL-1 $\beta$  or TNF- $\alpha$  reduced significantly the value to  $15.4 \pm 3.5 \%$ ,  $14.2 \pm 3.4 \%$ , respectively. By contrast, the administration of Preparation Example 13 compound by 1 or 3 mg/kg/day significantly increased the value to  $36.1 \pm 4.5 \%$ ,  $38.1 \pm 8.1 \%$  (IL-1 $\beta$ ), and  $29.1 \pm 4.7 \%$ ,  $28.9 \pm 4.5 \%$  (TNF- $\alpha$ ), respectively. Similarly, on day 6, while reticulocyte value of control group was  $16.3 \pm 3.1 \%$ , it was significantly reduced, by IL-1 $\beta$  administration or TNF- $\alpha$  administration, to  $12.2 \pm 2.0 \%$ ,  $9.4 \pm 3.3 \%$ , respectively. In contrast thereto, the oral administration of Preparation Example 13 compound by 1 or 3 mg/kg/day significantly improved to  $27.1 \pm 2.5 \%$ ,  $30.4 \pm 4.0 \%$  (IL-1 $\beta$ ), and  $23.3 \pm 3.3 \%$ ,  $26.8 \pm 7.5 \%$  (TNF- $\alpha$ ), respectively.

Fig. 6 shows the effect of the compound on EPO amount in serum. In this figure, the value of the column indicates [average value + standard deviation]. While the EPO amount of control group on day 3 was  $23.7 \pm 31.0$  mU/mL, the administration of IL-1 $\beta$  or TNF- $\alpha$  reduced significantly the EPO amount to  $5.9 \pm 14.3$  mU/mL,  $2.7 \pm 4.6$  mU/mL. By contrast, the administration of Preparation Example 13 compound by 1 or 3 mg/kg/day significantly increased the value to  $41.8 \pm 28.3$  mU/mL,  $58.9 \pm 21.1$  mU/mL (IL-1 $\beta$ ), and  $61.4 \pm 70.4$  mU/mL,  $64.7 \pm 92.2$  mU/mL (TNF- $\alpha$ ), respectively. Especially, with regard to the group of IL-1 $\beta$  administration, the improvement of EPO by administration of Preparation Example 13 compound was significant at 1 and 3 mg/kg/day. Similarly, on day 6, while EPO amount of control group was  $24.8 \pm 33.8$  mU/mL, it was significantly reduced, by IL-1 $\beta$  administration or TNF- $\alpha$  administration, to  $2.9 \pm 5.0$  mU/mL,  $3.3 \pm 6.0$  mU/mL, respectively. In contrast thereto, the oral administration of Preparation Example 13 compound by 1 or 3 mg/kg/day significantly improved to  $22.2 \pm 32.8$  mU/mL,  $37.1 \pm 31.1$  mU/mL (IL-1 $\beta$ ), and  $57.4 \pm 23.9$  mU/mL,  $69.9 \pm 37.8$  mU/mL (TNF- $\alpha$ ), respectively. Especially, with regard to the group of TNF- $\alpha$  administration, the improvement of EPO by administration of Preparation Example 13 compound was significant at 1 and 3 mg/kg/day.

The above results has indicated that the Preparation Example 13 compound enhances, in mice model of anemia of chronic disease, EPO production, promotes differentiation to erythrocytes, thereby improving the condition of anemia.
